

GEUS

3-D Geological modelling in Svendborg, DK: Model improvements gained by adding data from geotechnical and environmental investigations

Peter B. E. Sandersen, Geologist

Dept. of Groundwater mapping and Quaternary Geology

Geological Survey of Denmark and Greenland
Ministry of Climate and Energy

Expert Workshop, Oct. 8-9, 2012

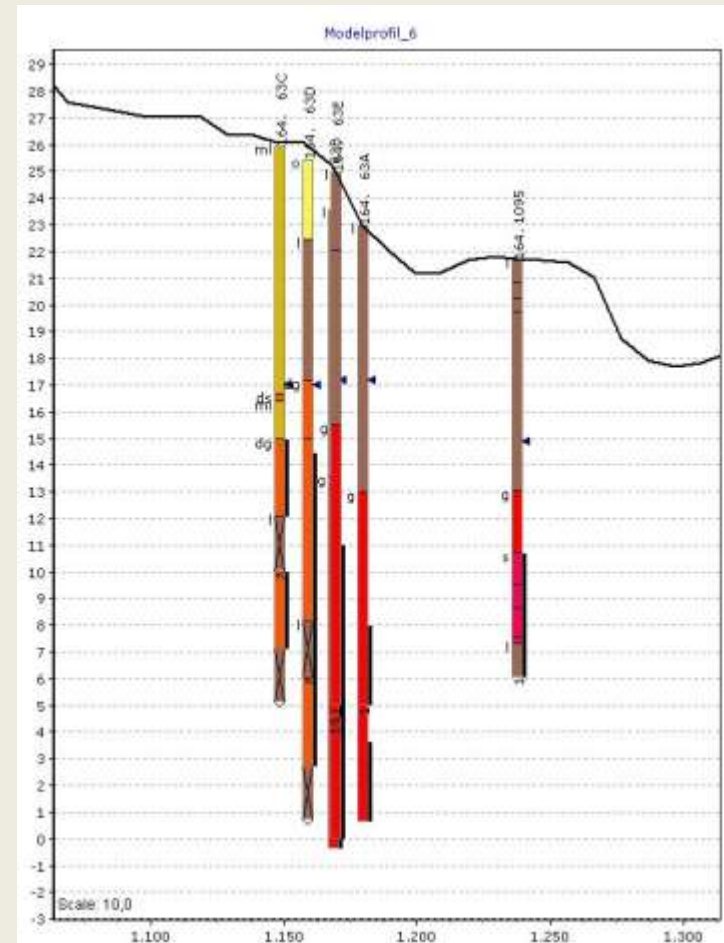

City of Svendborg

- Contamination from point sources
- Risk assessments related to waterworks
- Prioritize remediation
- Detailed 3-D geological modelling
- 3-D modelling requires dense data grids
- No geophysics
- Borehole data

Available data

- Borehole data from The National Jupiter database hosted by GEUS
- Borehole data from geotechnical and environmental investigations
- Local databases in other formats (Access, GeoGIS etc.)
- 3-D geological modelling software uses Jupiter-format (GeoScene 3D)
- Conversion of data to Jupiter-format

Challenges

- Borehole data in local databases
 - Different database formats
 - Different procedures for storage of data (errors and inconsistencies)
 - Purpose of storing?
 - Different purposes of drilling campaigns (geotechnical, environmental, etc.)
 - Varying degree of detail (inconsistencies)
- Can sufficient data be extracted automatically or is manual processing necessary?
- One iteration..... or many?

Converting borehole data to Jupiter format

General procedure:

1. Search in different local databases
2. Conversion of coordinate system
3. Checking redundancy
4. Comparison of formats
5. Automatic extraction of columns that fit the Jupiter-format
6. Manual processing of other columns; e.g. lithology (translation of descriptions)
7. Manual control of borehole location (GIS)
8. Visualization/control of borehole in 3-D software

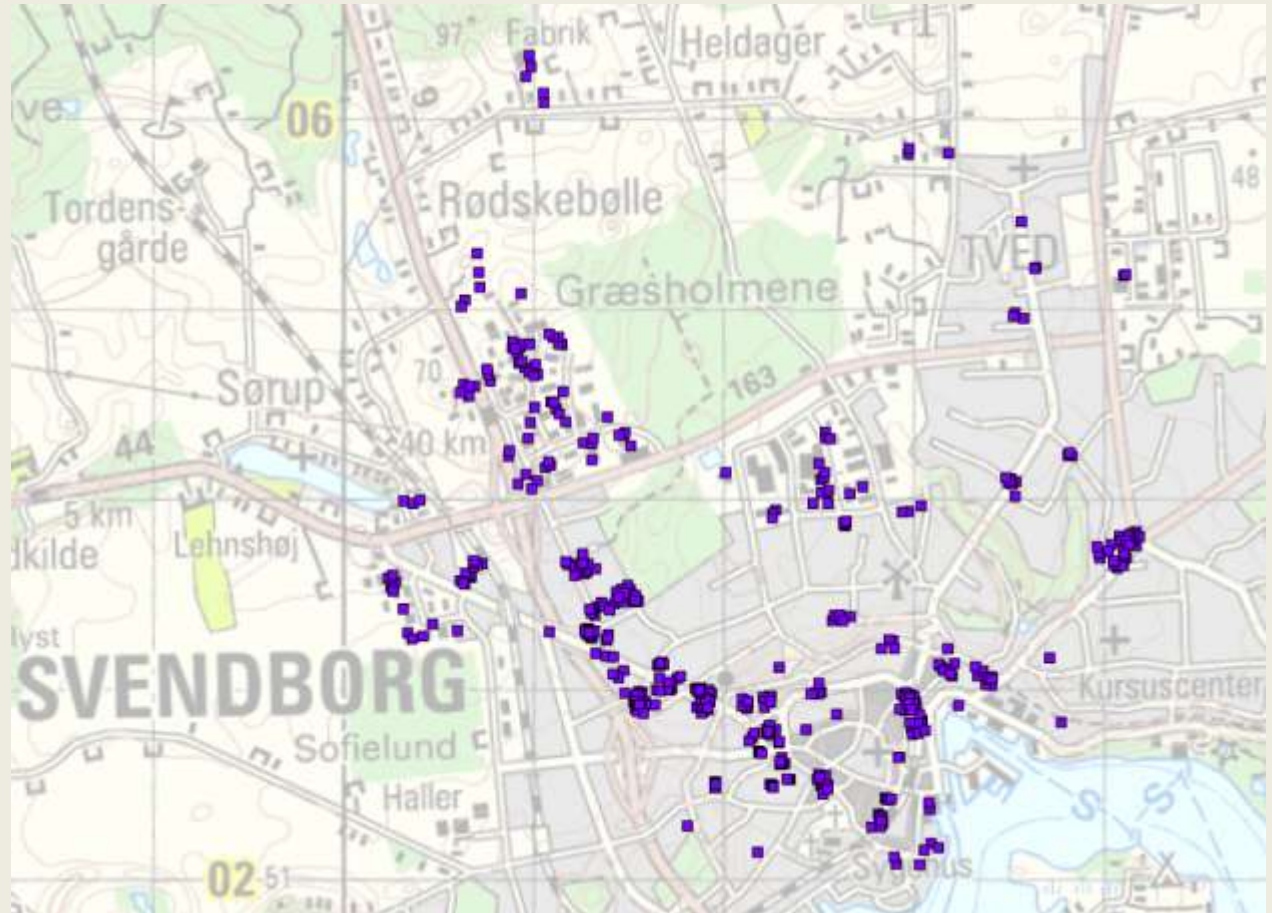

Boreholes in Jupiter database

- 260 boreholes

Boreholes in other databases

- 639 boreholes

All boreholes

- 899 boreholes

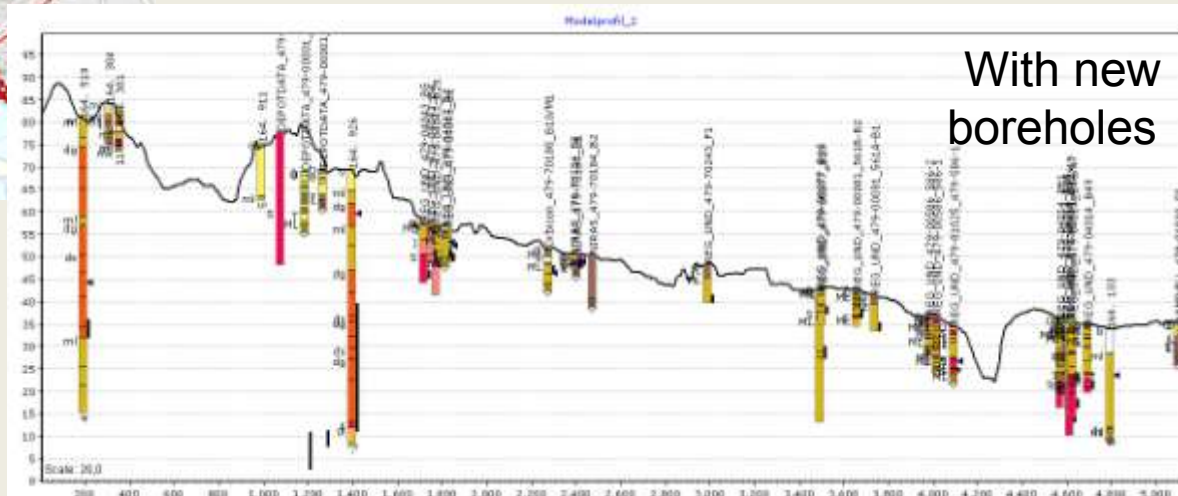

Profile 2

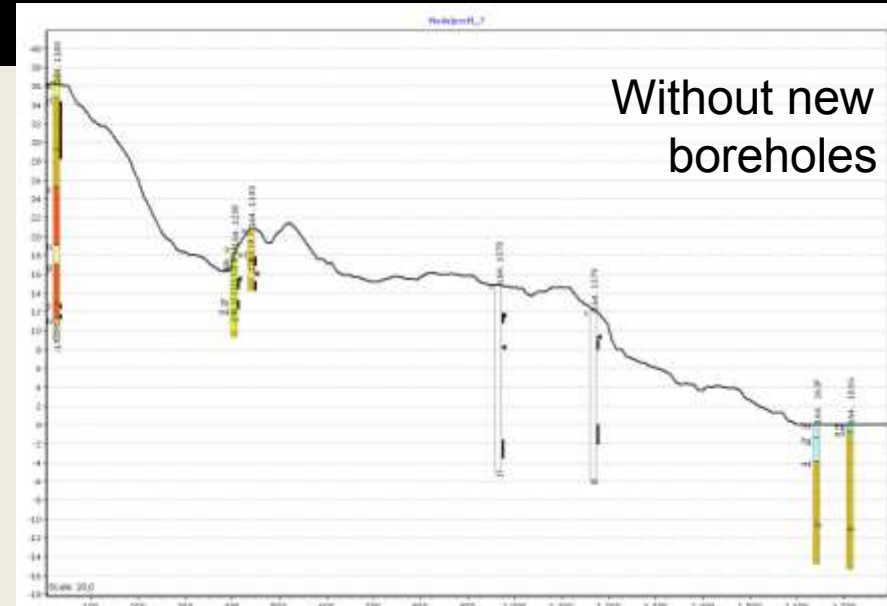

Without new boreholes

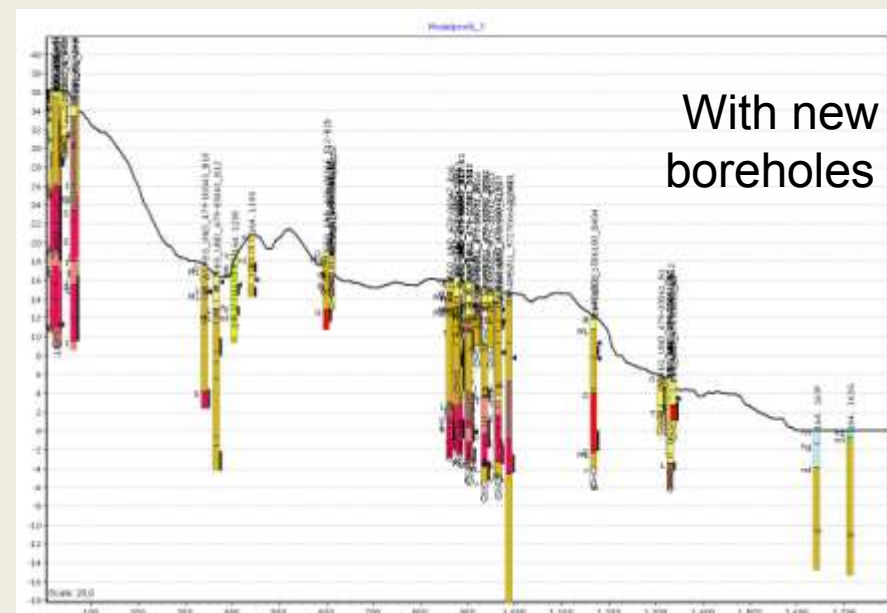

With new boreholes

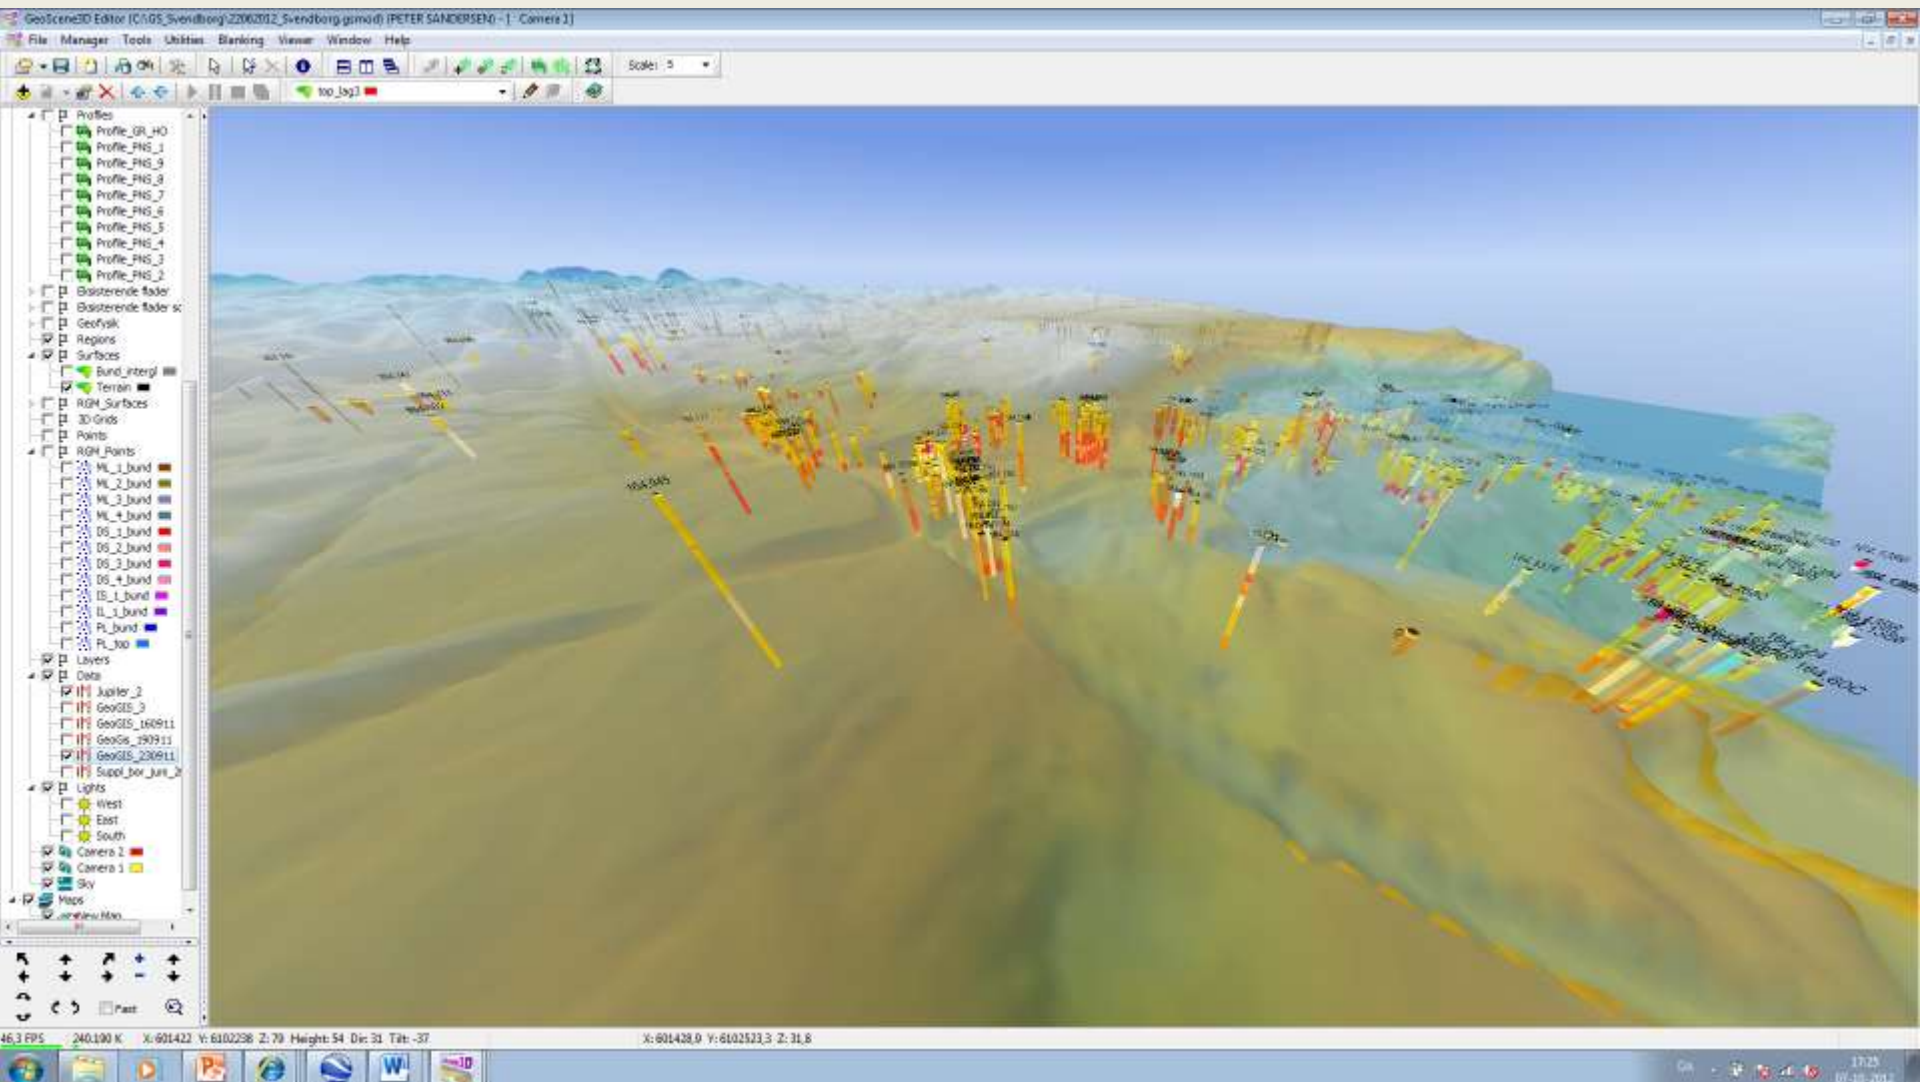

Profile 7

Without new boreholes

With new boreholes

Problems with “new” boreholes

- Inconsistent use of columns in databases
- Many boreholes do not have Z-coordinate (adjustment to DEM)
- Inconsistent lithological descriptions – in some cases no descriptions at all!
- Measurements of hydraulic head
 - Many screens in clay till (environmental and geotechnical investigations)
 - Unreliable measurements of hydraulic head (not related to aquifers)
 - Manual sorting necessary
- A full conversion is VERY time consuming!

Conclusions

Pros:

- Significantly larger amounts of data for the modelling
- Higher degree of detail of data (drilling methods)
- Supplementary information (strength, water content....)

Cons:

- Time consuming detective work (finding borehole data)
- Redundant data
- Time consuming conversion between formats
- Different levels of conversions
- Time consuming QA

Conclusions

- The Pros outweigh the Cons
- The 3-D modelling would have a high degree of uncertainty without the supplementary boreholes
- Better models – more accurate risk assessments

Actions

- Initiatives on a project scale/a national scale is needed
- Conversion of old data to a common format
- Initiatives to secure future use of a common format
- The work has started!
